1 Introduction

Given the opportunity to review the design document and related smart contract source code of the Wombat protocol, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts is well designed and engineered, though it can be further improved by addressing our suggestions. This document outlines our audit results.

1.1 About Wombat v3

The Wombat is a BNB-native stableswap protocol with open-liquidity pools, low slippage and single-sided staking. It brings greater capital efficiency to fuel DeFi growth and adoption. The new Wombat protocol introduces a new emissions distribution mechanism, which allows the veWOM holders to vote on how WOM emissions can be distributed to different gauges. The basic information of the audited protocol is as follows:

1.2 About PeckShield

PeckShield Inc. [7] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

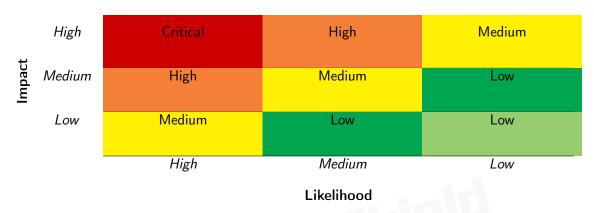

Table 1.2: Vulnerability Severity Classification

1.3 Methodology

To standardize the evaluation, we define the following terminology based on the OWASP Risk Rating Methodology [6]:

- <u>Likelihood</u> represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a checklist of items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract

is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- <u>Semantic Consistency Checks</u>: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [5], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings. Moreover, in case there is an issue that may affect an active protocol that has been deployed, the public version of this report may omit such issue, but will be amended with full details right after the affected protocol is upgraded with respective fixes.

1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary
Configuration	Weaknesses in this category are typically introduced during
	the configuration of the software.
Data Processing Issues	Weaknesses in this category are typically found in functional-
	ity that processes data.
Numeric Errors	Weaknesses in this category are related to improper calcula-
	tion or conversion of numbers.
Security Features	Weaknesses in this category are concerned with topics like
	authentication, access control, confidentiality, cryptography,
	and privilege management. (Software security is not security
	software.)
Time and State	Weaknesses in this category are related to the improper man-
	agement of time and state in an environment that supports
	simultaneous or near-simultaneous computation by multiple
	systems, processes, or threads.
Error Conditions,	Weaknesses in this category include weaknesses that occur if
Return Values,	a function does not generate the correct return/status code,
Status Codes	or if the application does not handle all possible return/status
	codes that could be generated by a function.
Resource Management	Weaknesses in this category are related to improper manage-
	ment of system resources.
Behavioral Issues	Weaknesses in this category are related to unexpected behav-
	iors from code that an application uses.
Business Logic	Weaknesses in this category identify some of the underlying
	problems that commonly allow attackers to manipulate the
	business logic of an application. Errors in business logic can
	be devastating to an entire application.
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used
	for initialization and breakdown.
Arguments and Parameters	Weaknesses in this category are related to improper use of
	arguments or parameters within function calls.
Expression Issues	Weaknesses in this category are related to incorrectly written
	expressions within code.
Coding Practices	Weaknesses in this category are related to coding practices
	that are deemed unsafe and increase the chances that an ex-
	ploitable vulnerability will be present in the application. They
	may not directly introduce a vulnerability, but indicate the
	product has not been carefully developed or maintained.

2 | Findings

2.1 Summary

Here is a summary of our findings after analyzing the implementation of the Wombat smart contracts. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logic, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings
Critical	0
High	0
Medium	2
Low	2
Informational	0
Total	4

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 2 medium-severity vulnerabilities and 2 low-severity vulnerabilities.

Title Status ID Severity Category PVE-001 Revisited Logic to Distribute WOM Medium **Business Logic** Fixed emissions in MasterWombat **PVE-002** Medium massUpdatePools Fixed Timely Business Logic basePartition Update **PVE-003** Low Timely Update of base/voteIndex in **Business Logic** Fixed resumeAll() PVE-004 Trust Issue of Admin Keys Security Features Low Mitigated

Table 2.1: Key Wombat v3 Audit Findings

Beside the identified issues, we emphasize that for any user-facing applications and services, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms should kick in at the very moment when the contracts are being deployed on mainnet. Please refer to Section 3 for details.

3 Detailed Results

3.1 Revisited Logic to Distribute WOM emissions in MasterWombat

• ID: PVE-001

Severity: MediumLikelihood: MediumImpact: Medium

• Target: MasterWombatV3

Category: Business Logic [4]CWE subcategory: CWE-841 [2]

Description

The Wombat protocol introduces a new emissions distribution mechanism, which allows the veWOM holders to vote on how WOM emissions can be distributed to different gauges according to the allocation and voting weight. The MasterWombatV3 contract is responsible to claim WOM emissions from the Voter contract and distribute them to users.

To elaborate, we show below the code snippet of the _updatePool() routine, which is invoked at the beginning of each operation (e.g., deposit/withdraw) to claim wom emissions from the Voter contract and accumulate the accwomPerShare/ accwomPerFactorShare. By design, the new claimed emissions shall be rewarded into the next reward duration. However, current implementation invokes the IVoter(voter).distribute() (line 218) first to claim the emissions and update the rewardRate, then invokes the calRewardPerUnit() (line 221) to accumulate the accwomPerShare/ accwomPerFactorShare are accumulated per the new rewardRate, not the expected old rewardRate. Our analysis shows that it shall accumulate the accwomPerShare/ accwomPerFactorShare before the claiming of new emissions in the _updatePool() routine.

```
function _updatePool(uint256 _pid) private {
   PoolInfo storage pool = poolInfo[_pid];
   IVoter(voter).distribute(address(pool.lpToken));

if (block.timestamp > pool.lastRewardTimestamp) {
```

Listing 3.1: MasterWombatV3:: updatePool()

Moreover, the notifyRewardAmount() routine is invoked indirectly from the Voter::distribute() routine. It is used to notify the MasterWombatV3 contract to update the pool.rewardRate and the pool. periodFinish. However, it comes to our attention that it also updates the pool.lastRewardTimestamp to block.timestamp. As a result, it bypasses the accumulation of the accWomPerShare/ accWomPerFactorShare in the the _updatePool() routine, as the condition if (block.timestamp > pool.lastRewardTimestamp) (line 220) becomes false.

```
233
         function notifyRewardAmount(address lpToken, uint256 amount) external override {
234
             require( amount > 0, 'notifyRewardAmount: zero amount');
236
             // this line reverts if asset is not in the list
237
             uint256 pid = assetPid[ lpToken] - 1;
238
             PoolInfo storage pool = poolInfo[pid];
239
             if (block.timestamp >= pool.periodFinish) {
240
                 \verb|pool.rewardRate| = to128(\_amount / REWARD DURATION);
241
             } else {
                 uint256 remainingTime = pool.periodFinish - block.timestamp;
242
243
                 uint256 leftoverReward = remainingTime * pool.rewardRate;
244
                 pool.rewardRate = to128((\_amount + leftoverReward) / REWARD\_DURATION);
             }
245
247
             pool.lastRewardTimestamp = uint40(block.timestamp);
248
             pool.periodFinish = uint40(block.timestamp + REWARD DURATION);
249
250
```

Listing 3.2: MasterWombatV3::notifyRewardAmount()

Recommendation Revisit the above mentioned logic to accumulate the accWomPerShare/accWomPerFactorShare first per current reward rate, then claim the new emissions for the next reward duration.

Status The issue has been fixed by these commits: 9029448 and 2f29c2b.

3.2 Timely massUpdatePools During basePartition Update

• ID: PVE-002

Severity: MediumLikelihood: Medium

• Impact: Medium

• Target: MasterWombatV3

• Category: Business Logic [4]

• CWE subcategory: CWE-841 [2]

Description

In the Wombat protocol, the MasterWombatV3 contract is responsible to claim the WOM emissions from the Voter contract and distribute them to users. The claimed emissions are divided to two partitions, that are the base partition emissions and the boosted partition emissions. The base partition emissions are distributed to users per the amounts of their deposited LPs, and the boosted partition emissions are distributed per users boosted factors.

The amount of base partition emissions is calculated from all the claimed emissions per the percentage basePartition, which can be dynamically updated by the owner via the updateEmissionPartition () routine. While analyzing the logic to update the basePartition in the updateEmissionPartition() routine, we notice the need of timely invoking the massUpdatePools() routine to accumulate the accWomPerShare/accWomPerFactorShare before the new basePartition gets effective.

```
function updateEmissionPartition(uint16 _basePartition) external onlyOwner {
require(_basePartition <= 1000);
basePartition = _basePartition;
emit UpdateEmissionPartition(msg.sender, _basePartition, 1000 - _basePartition);
498
}
```

Listing 3.3: MasterWombatV3::updateEmissionPartition()

If the call to the massUpdatePools() is not immediately invoked before the new basePartition gets effective, certain situations may be crafted to create an unfair reward distribution. Fortunately, this interface is restricted to the owner (via the onlyOwner modifier), which greatly alleviates the concern.

Recommendation Timely invoke the massUpdatePools() at the beginning of the updateEmissionPartition () routine.

Status The issue has been fixed by this commit: 0e92140.

3.3 Timely Update of base/voteIndex in resumeAll()

• ID: PVE-003

• Severity: Low

Likelihood: Low

• Impact: Medium

• Target: Voter

• Category: Business Logic [4]

• CWE subcategory: CWE-841 [2]

Description

In the Wombat protocol, the Voter contract implements the gauge voting, which veWOM holders can participate in to apply new allocation for their votes. They can allocate their vote (1 veWOM = 1 vote) to one or more gauges. The WOM emission to a gauge is proportional to the amount of vote it receives. Specially, the WOM emission to a gauge can be paused by the owner. When a gauge is paused, its un-distributed rewards are forfeited, though users can still vote/unvote and receive bribes.

To elaborate, we show below the code snippets of the resume()/resumeAll() routines, which are used to resume the paused gauge(s). Because the un-distributed rewards to a paused gauge are forfeited, so when the gauge is resumed in the resume() routine, it invokes the _distributeWom() (line 317) and updates its supplyBaseIndex/supplyVoteIndex to the latest. However, in the resumeAll () routine, which is used to resume all paused gauges, it doesn't catch up the supplyBaseIndex/supplyVoteIndex of each paused gauge to the latest. As a result, the un-distributed rewards when the gauge is paused are still available. Based on this, we suggest to update the supplyBaseIndex/supplyVoteIndex to the latest for all the paused gauges in the resumeAll() routine.

```
312
         function resume(IERC20 lpToken) external onlyOwner {
313
             require(infos[ lpToken]. whitelist == false, 'voter: not paused');
314
             _checkGaugeExist(_lpToken);
316
             // catch up supplyVoteIndex
317
             distributeWom();
318
             infos[ lpToken].supplyBaseIndex = baseIndex;
319
             infos[ lpToken].supplyVoteIndex = voteIndex;
320
             infos[_lpToken].whitelist = true;
321
         }
323
         function resumeAll() external onlyOwner {
324
             unpause();
325
```

Listing 3.4: Voter. sol

Recommendation Revisit the logic in the resumeAll() routine to forfeit the un-distributed rewards by catching up the supplyBaseIndex/supplyVoteIndex of each paused gauge to the latest.

Status The issue has been fixed by this commit: 9844fcd.

3.4 Trust Issue of Admin Keys

ID: PVE-004

• Severity: Low

• Likelihood: Low

• Impact: Medium

• Target: Multiple contracts

• Category: Security Features [3]

• CWE subcategory: CWE-287 [1]

Description

In the Wombat protocol, there is a privileged account, i.e., owner, that plays a critical role in governing and regulating the system-wide operations (e.g., set WOM emission speed). Our analysis shows that this privileged account needs to be scrutinized. In the following, we use the Voter contract as an example and show the representative functions potentially affected by the privileges of the owner account.

Specifically, the privileged functions in Voter allow for the owner to set the WOM emission rate, pause/unpause gauge(s), set the gauge manager/bribe address for a LP, emergency withdraw the WOM in the contract, etc.

```
95
         function setWomPerSec(uint88 _womPerSec) external onlyOwner {
96
             require(_womPerSec <= 10000e18, 'reward rate too high'); // in case 'voteIndex'</pre>
                 overflow
97
             _distributeWom();
98
             womPerSec = _womPerSec;
99
        }
100
        /// @notice Pause emission of WOM tokens. Un-distributed rewards are forfeited
101
         /// Users can still vote/unvote and receive bribes.
102
103
         function pause(IERC20 _lpToken) external onlyOwner {
104
             require(infos[_lpToken].whitelist, 'voter: not whitelisted');
105
             _checkGaugeExist(_lpToken);
106
107
             infos[_lpToken].whitelist = false;
108
        }
109
110
        /// @notice Resume emission of WOM tokens
111
         function resume(IERC20 _lpToken) external onlyOwner {
112
             require(infos[_lpToken].whitelist == false, 'voter: not paused');
113
             _checkGaugeExist(_lpToken);
114
115
             // catch up supplyVoteIndex
116
             _distributeWom();
117
             infos[_lpToken].supplyBaseIndex = baseIndex;
118
             infos[_lpToken].supplyVoteIndex = voteIndex;
```

```
119
             infos[_lpToken].whitelist = true;
120
        }
121
122
         /// @notice Pause emission of WOM tokens for all assets. Un-distributed rewards are
123
         /// Users can still vote/unvote and receive bribes.
124
         function pauseAll() external onlyOwner {
125
             _pause();
126
127
128
         /// Onotice Resume emission of WOM tokens for all assets
         function resumeAll() external onlyOwner {
129
130
             _unpause();
131
132
133
         /// @notice get gaugeManager address for LP token
134
         function setGauge(IERC20 _lpToken, IGauge _gaugeManager) external onlyOwner {
135
             require(address(_gaugeManager) != address(0));
136
             _checkGaugeExist(_lpToken);
137
138
             infos[_lpToken].gaugeManager = _gaugeManager;
139
        }
140
141
        /// @notice get bribe address for LP token
142
         function setBribe(IERC20 _lpToken, IBribe _bribe) external onlyOwner {
143
             _checkGaugeExist(_lpToken);
144
145
             infos[_lpToken].bribe = _bribe; // 0 address is allowed
146
        }
147
148
        /// @notice In case we need to manually migrate WOM funds from Voter
149
         /// Sends all remaining wom from the contract to the owner
150
         function emergencyWomWithdraw() external onlyOwner {
151
             // SafeERC20 is not needed as WOM will revert if transfer fails
152
             wom.transfer(address(msg.sender), wom.balanceOf(address(this)));
153
```

Listing 3.5: Example Privileged Operations in the Voter Contract

We understand the need of the privileged functions for contract maintenance, but at the same time the extra power to the owner may also be a counter-party risk to the protocol users. It is worrisome if the privileged owner account is a plain EOA account. Note that a multi-sig account could greatly alleviate this concern, though it is still far from perfect. Specifically, a better approach is to eliminate the administration key concern by transferring the role to a community-governed DAO.

Recommendation Promptly transfer the privileged account to the intended DAO-like governance contract. All changed to privileged operations may need to be mediated with necessary timelocks. Eventually, activate the normal on-chain community-based governance life-cycle and ensure the intended trustless nature and high-quality distributed governance.

 ${\bf Status} \quad \hbox{This issue has been mitigated as the team confirmed they use multi-sig for the $\tt owner account.}$

4 Conclusion

In this audit, we have analyzed the design and implementation of the Wombat v3 protocol which is introduced on top of the Wombat v2 with new feature to allow the veWOM holders to vote on how WOM emissions can be distributed to different gauges. The current code base is well structured and neatly organized. Those identified issues are promptly confirmed and addressed.

Moreover, we need to emphasize that Solidity-based smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
